

What happens when fiber optic cable pins are inserted

Overview

Joining fiber optic cables is typically done through splicing, which can be mechanical or fusion. Mechanical splicing involves aligning the fiber ends and using a connector to hold them together, while fusion splicing uses heat to fuse the fiber ends, creating a continuous fiber. In MPO and MTP fiber connector systems, Male vs Female and Pin vs No-Pin describe the same core engineering attribute: the presence or absence of alignment pins on the MT ferrule. Unlike single-fiber connectors such as LC or SC, this distinction is not optional terminology but a mandatory. Proper fiber optic cable installation is critical to ensuring network performance and long-term reliability. This article outlines three key errors and how to avoid them. It is crucially clean before it is inserted into a transmitter or receiver. Dust, lint, oil (from touching the fiber end face), or other foreign particles obscure the end face, compromising the integrity of the optical signal being sent over the fiber. But the physical difference in the copper and the glass conductors require different handling procedures.
